## Basics: ALI

Category	Description	Neuromuscular Findings	Doppler	Intervention
I	Viable	No sensory or muscle weakness	Audible arterial and venous	Elective
IIa	Threatened (marginally)	Minimal	Often inaudible arterial, audible venous	Urgent
IIb	Threatened (immediately)	Mild to moderate, associated with pain	Usually inaudible arterial, audible venous	Emergent
III	Irreversible	Profound deficit	No signals	Emergent

## Tried and True

### Editor's Choice – European Society for Vascular Surgery (ESVS) 2020 Clinical Practice Guidelines on the Management of Acute Limb Ischaemia

**Recommendation 14**

It is recommended that patients with acute limb ischaemia should have access to treatment in a hybrid theatre, or operating theatre with C arm equipment, and by a clinical team able to offer a full range of open or endovascular interventions during a single procedure.

Class	Level	References
I	C	Consensus

**Recommendation 15**

For patients requiring surgical thrombo-embolectomy for acute limb ischaemia, regional or local anaesthesia may be considered, but always with an anaesthetist present.

Class	Level	References
IIb	C	Morris-Stiff et al. (2009) <sup>18</sup>

**Recommendation 21**

After open revascularisation for acute limb ischaemia, simultaneous endovascular treatment addressing inflow or outflow stenosis should be considered.

**Open surgical or endovascular revascularization for acute limb ischemia**

John C. Wang, MD, FACS, Ann H. Kim, MD, and Vikram S. Kashyap, MD, FACS, Cleveland, Ohio

Acute limb ischemia (ALI) is one of the most common vascular emergencies, with high risk for limb loss if it is not treated expeditiously. Endovascular therapy is less invasive and used increasingly because of patient factors that disfavor open surgery despite limited quality data to support its safety and efficacy. This evidence summary reviews literature from 1990 to 2014, comparing contemporary surgical and endovascular revascularization. Systematic review was performed with emphasis on acuity of presentation, study design, revascularization techniques, limb salvage and mortality rates, and complications. There were 2999 articles identified and 563 abstracts reviewed; 68 articles were reviewed fully and 26 critically appraised. Limb salvage, amputation-free survival, overall survival and mortality, and treatment complications were elucidated, including Medicare outcomes data. Risk factors for amputation and mortality were identified. Surgical or endovascular revascularization for ALI is achievable with acceptable limb salvage and amputation rates, which are not markedly different between the two modalities in the short term. Endovascular therapy and surgery are complementary rather than competing strategies for ALI. Further good-quality clinical trial data are needed to define longer term outcomes. (J Vasc Surg 2016;63:270-8.)

**BMC2 Registry Data**

- Retrospective review of open thrombectomy procedures
- N = 954 unique patients with complete discharge information.
- Discharge dates range from 2018 - 2021.

### Cases Illustration

60 yo man with known Afib, taken off DOAC for colonoscopy. Presents to ER with 4 hours of painful, numb RLE. On exam, non palp fem pulse. Has SVS grade IIB ischemia. Heparinized, aspirin, and IV hydration. Taken to the hybrid OR. **What would you do?**

75 yo woman with known PAD, prior ABI = R 0.9 / L 0.5 with R femoral to AK popliteal ePTFE graft. Presents with SVS IIA/B ischemia. Heparinized, IVF hydration. Taken to the hybrid OR. **What would you do?**

- ### Summary
- Recognition is key!
  - Prompt anticoagulation and hydration
  - Consider patient's underlying illnesses
  - Optimal therapy is rendered in Hybrid suite
  - If clearly embolic, would proceed with open thrombectomy
  - If **not** clearly embolic, prior PAD, prior graft, peripheral AA, would proceed with endoluminal therapy
  - Evidence is insufficient to recommend endo or thrombectomy in all cases of ALI
  - **Caveot** – ALI is often less acute than one may think!
